As a non-parametric test, the KS test can be applied to compare any two distributions regardless of whether you assume normal or uniform. In practice, the KS test is extremely useful because it is efficient and effective at distinguishing a sample from another sample, or a theoretical distribution such as a normal or uniform distribution.

Note that the distribution of the first population has one parameter. Let q be the probability that a randomly-chosen member of the second population is in category #1. Note that the distribution of the second population also has one parameter. To compare the distributions of the two populations, we construct two different models.

The comparative CDF plot shows the empirical distributions. The horizontal axis indicates the range of the data: [0, 11] for the Gamma variable, [-3,3] for the Normal variable, and [-0.5, 0.5] for the Uniform variable. However, the plot is far from perfect.

for an example. We can theoretically show that if F1 is the empirical distribution of xand F2 is the true distribution xwas drawn from, then lim n!1D n = 0. Similarly, if the two distributions have no overlap at all, the maximum di erence will be 1 (when one CDF is 1 and the other is 0). Therefore, we can test distribution equality by comparing ...
